1.9.2. Diagramas de Pourbaix

1.9.2.1. Construcción del diagrama de Pourbaix del hierro

Tabla 28 Reacciones consideradas en el sistema significantes en el proceso de corrosión

Information needed: $E^{\ominus} = -0.440$ V SHE.

Apply the Nernst Eqn: $E = -0.440 - \frac{0.0591}{2} \cdot \log \frac{1}{a_{Fe^{2+}}}$
 $= -0.440 + 0.0295 \log(a_{Fe^{2+}})$

Figura 131 Diagrama de Pourbaix del Sistema Fe – H2O

Information needed: $E^{\ominus} = -0.085$ V SHE.

Apply the Nernst Eqn: $E = -0.085 - \frac{0.0591}{8} \cdot \log \frac{1}{(a_{H^+})^8}$
 $= -0.085 - 0.0591$ pH

Information needed: $E^{\ominus} = +0.221$ V SHE.

Apply Nernst Eqn: $E = +0.221 - \frac{0.0591}{2} \cdot \log \frac{1}{(a_{H^+})^2}$
 $= 0.221 - 0.0591$ pH

Information needed: $E^{\ominus} = +0.980$ V SHE.

Apply the Nernst Eqn: $E = +0.980 - \frac{0.0591}{2} \cdot \log \frac{(a_{Fe^{2+}})^3}{(a_{H^+})^8}$
 $= 0.980 - 0.2364$ pH $- 0.0886 \log(a_{Fe^{2+}})^3$

Information needed: $E^{\ominus} = +0.771$ V SHE.

Apply the Nernst Eqn: $E = +0.771 - \frac{0.0591}{1} \cdot \log \frac{(a_{Fe^{2+}})}{(a_{Fe^{3+}})}$
 $= 0.771 + 0.0591 \log(a_{Fe^{3+}}) - 0.0591 \log(a_{Fe^{2+}})$

Information needed: $E^{\ominus} = +0.728$ V SHE.

Apply the Nernst Eqn: $E = +0.728 - \frac{0.0591}{2} \cdot \log \frac{(a_{Fe^{2+}})^2}{(a_{H^+})^6}$
 $= 0.728 - 0.1773$ pH $- 0.0591 \log(a_{Fe^{2+}})$

Information needed: $(a_{H^+})^6 / (a_{Fe^{3+}})^2 = 10^2$

Taking logarithms: $6 \log(a_{H^+}) - 2 \log(a_{Fe^{3+}}) = 2$

Hence, rearranging: $pH = \{- \log(a_{Fe^{3+}}) - 1\} / 3$

1.9.5. Importancia de la protección contra la corrosión

La protección contra la corrosión depende principalmente del diseño inicial y del mantenimiento de los equipos que se encuentran en presencia de un ambiente fisicoquímico corrosivo.

Explosión de una tubería de aguas negras, México

Un ejemplo de daños de corrosión con responsabilidades compartidas fue la explosión que ocasionó la muerte de más de 200 personas en Guadalajara, México, en abril 1992. Además de las fatalidades, la serie de explosiones dañó 1600 edificios y lesionó 1500 personas. Los costos por los daños fueron estimados en 75 MM \$. La explosión fue rastreada hasta la instalación de una tubería de agua por una contratista varios años antes de la explosión que produjo una fuga de agua sobre una línea de gasolina subterránea. La corrosión subsecuente de la tubería de gasolina, produjo la fuga de gasolina dentro de las tuberías de aguas negras.

1.9.8. Descripción de aleaciones utilizadas para la prevención de corrosión

Hastelloy C-276 (N10276)

Description and corrosion resistance. This is a nickel-chromium-molybdenum wrought alloy that is considered the most versatile corrosion-resistant alloy available. It is resistant to the formation of grain boundary precipitates in the weld heat-affected zone, thus making it suitable for most chemical process applications in an as-welded condition. Alloy C-276 also has excellent resistance to pitting, stress-corrosion cracking, and oxidizing atmospheres up to 1050°C. It has exceptional resistance to a wide variety of chemical environments and outstanding resistance to a wide variety of chemical process environments including ferric and cupric chlorides, hot contaminated mineral acids, solvents, chlorine and chlorine contamination (both organic and inorganic), dry chlorine, formic and acetic acids, acetic anhydride, seawater and brine solutions, and hypochlorite and chlorine dioxide solutions. It is one of the few alloys resistant to wet chloride gas, hypochlorite, and chlorine dioxide solutions and has exceptional resistance to strong solutions of oxidizing salts, such as ferric and cupric chlorides.

Applications. Some typical applications include equipment components in chemical and petrochemical organic chloride processes and processes utilizing halide or acid catalysts. Other industry applications are pulp and paper digesters and bleach areas, scrubbers and ducting for flue gas desulfurization, pharmaceutical and food processing equipment.

Incoloy 800 (N08800)

Description and corrosion resistance. Alloy 800 is a nickel-iron-chromium alloy with good strength and excellent resistance to oxidation and carburization in high-temperature atmospheres. It also resists corrosion by many aqueous environments. The alloy maintains a stable, austenitic structure during prolonged exposure to high temperatures.

Applications. Uses for Incoloy 800 include

- Process piping
- Heat exchangers
- Carburizing equipment
- Heating-element sheathing
- Nuclear steam-generator tubing

 Inconel 600 (N06600)

Description and corrosion resistance. Alloy 600 is a nickel-chromium alloy designed for use from cryogenic to elevated temperatures in the range of 1093°C. The high nickel content of the alloy enables it to retain considerable resistance under reducing conditions and makes it resistant to corrosion by a number of organic and inorganic compounds. The nickel content gives it excellent resistance to chloride-ion stress corrosion cracking and also provides excellent resistance to alkaline solutions.

Its chromium content gives the alloy resistance to sulfur compounds and various oxidizing environments. The chromium content of the alloy makes it superior to commercially pure nickel under oxidizing conditions. In strong oxidizing solutions like hot, concentrated nitric acid, 600 has poor resistance. Alloy 600 is relatively unattacked by the majority of neutral and alkaline salt solutions and is used in some caustic environments. The alloy resists steam and mixtures of steam, air, and carbon dioxide.

Alloy 600 is nonmagnetic, has excellent mechanical properties and a combination of high strength and good workability, and is readily weldable. Alloy 600 exhibits cold-forming characteristics normally associated with chromium-nickel stainless steels. It is resistant to a wide range of corrosive media. The chromium content gives better resistance than Alloys 200 and 201 under oxidizing conditions, and at the same time the high nickel gives good resistance to reducing conditions. Other qualities are as follows:

Virtually immune to chlorine ion stress corrosion cracking.

Demonstrates adequate resistance to organic acids such as acetic, formic, and stearic. Excellent resistance to high purity water used in primary and secondary circuits of pressurized nuclear reactors.

Little or no attack occurs at room and elevated temperatures in dry gases, such as chlorine or hydrogen chloride. At temperatures up to 550°C in these media, this alloy has been shown to be one of the most resistant of the common alloys.

At elevated temperatures the annealed and solution annealed alloy shows good resistance to scaling and has high strength.

The alloy also resists ammonia-bearing atmospheres, as well as nitrogen and carburizing gases.

Under alternating oxidizing and reducing conditions the alloy may suffer from selective oxidation.

Applications. Typical corrosion applications include titanium dioxide production (chloride route), perchlorethylene syntheses, vinyl chloride monomer (VCM), and magnesium chloride. Alloy 600 is used in chemical and food processing, heat treating, phenol condensers, soap manufacture, vegetable and fatty acid vessels, among other uses. In nuclear reactors uses are for such components as control rod inlet stub tubes, reactor vessel components and seals, steam dryers, and separators in boiling water reactors. In pressurized water reactors it is used for control rod guide tubes and steam generator baffle plates. Other uses include

Thermocouple sheaths

Ethylene dichloride (EDC) cracking tubes

Conversion of uranium dioxide to tetrafluoride in contact with hydrofluoric acid

Production of caustic alkalis, particularly in the presence of sulfur compounds

Reactor vessels and heat-exchanger tubing used in the production of vinyl chloride

Process equipment used in the production of chlorinated and fluorinated hydrocarbons

Furnace retort seals, fans, and fixtures

Roller hearths and radiant tubes, in carbonitriding processes especially

Monel 400 (N04400)

Description and corrosion resistance. Alloy 400 is a nickel-copper alloy with excellent corrosion resistance in a wide variety of media. The alloy is characterized by good general corrosion resistance, good weldability, and moderate-to-high strength. The alloy has been used in a variety of applications. It has excellent resistance to rapidly flowing brackish water and seawater. It is particularly resistant to hydrochloric and hydrofluoric acids when they are deaerated. The alloy is slightly magnetic at room temperature and is widely used in the chemical, oil, and marine industries.

It has a good corrosion resistance in an extensive range of marine and chemical environments, from pure water to nonoxidizing mineral acids, salts, and alkalis. This alloy is more resistant than nickel under reducing conditions and more resistant than copper under oxidizing conditions. It does show, however, better resistance to reducing media than oxidizing ones. It also has

Good mechanical properties from subzero temperatures up to about 480°C.

Good resistance to sulfuric and hydrofluoric acids. Aeration, however, will result in increased corrosion rates. It may be used to handle hydrochloric acid, but the presence of oxidizing salts will greatly accelerate corrosive attack.

Resistance to neutral, alkaline, and acid salts is shown, but poor resistance is found with oxidizing acid salts such as ferric chloride.

Excellent resistance to chloride ion stress corrosion cracking.

Applications. Uses for Monel 400 include

Feed water and steam generator tubing

Brine heaters and seawater scrubbers in tanker inert gas systems

Sulfuric acid and hydrofluoric acid alkylation plants

Pickling bath heating coils

Heat exchangers in a variety of industries

Transfer piping from oil refinery crude columns

Plants for the refining of uranium and isotope separation in the production of nuclear fuel

Pumps and valves used in the manufacture of perchlorethylene, chlorinated plastics

Monoethanolamine (MEA) reboiling tubes

Cladding for the upper areas of oil refinery crude columns

Propeller and pump shafts

Nickel 200 (N02200)

Description and corrosion resistance. This is commercially pure wrought nickel with good mechanical properties over a wide range of temperature and excellent resistance to many corrosives, in particular hydroxides. Nickel 200 can be hot formed to almost any shape. A temperature range of 650 to 1230°C is recommended and should be carefully adhered to because the proper temperature is the most important factor in achieving hot malleability. Full information of the forming process should be sought and understood before proceeding. 200 can be cold formed by all conventional methods, but because nickel alloys have greater stiffness than stainless steels more power is required to perform the operations. Other properties are

Good resistance to corrosion in acids and alkalies and is most useful under reducing conditions

Outstanding resistance to caustic alkalis up to and including the molten state

In acid, alkaline, and neutral salt solutions the material shows good resistance, but in oxidizing salt solutions severe attack will occur

Resistant to all dry gases at room temperature and in dry chlorine and hydrogen chloride may be used in temperatures up to 550°C

Resistance to mineral acids varies according to temperature and concentration and whether the solution is aerated or not; corrosion resistance is better in deaerated acid

Applications. It is used in the following:

Manufacture and handling of sodium hydroxide, particularly at temperature above 300°C

Production of viscose rayon and manufacture of soap

Aniline hydrochloride production and the chlorination of aliphatic hydrocarbons such as benzene, methane and ethane

Manufacture of vinyl chloride monomer

Storage and distribution systems for phenol; immunity from any form of attack ensures absolute product purity

Reactors and vessels in which fluorine is generated and reacted with hydrocarbons

Nitronic 60 (S21800)

Description and corrosion resistance. Nitronic 60 is truly an all-purpose metal. This fully austenitic alloy was originally designed as a high-temperature alloy for temperatures around 980°C. The oxidation resistance of Nitronic 60 is similar to S30900 steel and far superior to S30400 steel. The additions of silicon and manganese have given the alloy a matrix to inhibit wear, galling, and fretting even in the annealed condition. Higher strengths are attainable through cold working the material, and it is still fully austenitic after severe cold working. This working does not enhance the antigalling properties as is normal for carbon steels and some stainless steels. The cold or hot work put into the material adds strength and hardness.

The chromium and nickel additions give it comparable corrosion to S30400 and S31600 stainless steels, while having a twice the yield strengths of regular stainless steels. The high mechanical strength in annealed parts permits use of reduced cross sections for weight and cost reductions. Although uniform corrosion resistance of Nitronic 60 is better than S30400 stainless in most environments, its yield strength is nearly twice that of S30400 and S31600 steels. Chloride pitting resistance is superior to that of type S31600 stainless; Nitronic 60 provides excellent high-temperature oxidation resistance and low-temperature impact.

Nitronic 60 is also readily welded using conventional joining processes. It can be handled similarly to S30400 and S31600 steels. No preheat or postweld heat treatments are necessary, other than the normal stress relief used in heavy fabrication. Most applications use Nitronic 60 in the as-welded condition, unless corrosion resistance is a consideration. Fillerless fusion welds (autogenous) have been made using GTA. These welds are free from cracking and have galling and cavitation resistance similar to the unwelded base metal. Heavy weld deposits using this process are sound and exhibit higher strength than the unwelded base metal. The metal-to-metal wear resistance of the GMA welds are slightly lower than the base metal wear resistance.

Applications. Applications using Nitronic 60 are valve stems, seats and trim, fastening systems, screening, pins, bushings and roller bearings, pump shafts, and rings. Other uses include wear plates, rails guides, and bridge pins. This alloy provides a significant lower-cost way to fight wear and galling compared to nickel- or cobalt-based alloys. It is also used for

Automotive valves; it can withstand gas temperatures of up to 820°C for a minimum of 80,000 km

Fastener galling; it is capable of frequent assembly and disassembly, allowing more use of the fastener before the threads are torn up and also helps to eliminate corroded or frozen fasteners

Pins; it is used in roller prosthetics and chains to ensure a better fit of parts (closer tolerance, nonlubricated) and a longer life

Marine shafts; it has better corrosion than types 304 and 316, with double the yield strength

Pin and hanger expansion joints for bridges; it has better corrosion, galling resistance, low-temperature toughness, and high charpy values at subzero temperatures compared to the A36 and A588 carbon steels commonly used.
